October 21, 2012

A history

Theorem (Popa, Shlyakhtenko, '03)

Given any Λ -lattice (or planar algebra), $\mathcal{P}$ there is a finite index inclusion of II_1 factors $N \subset M$ with $N, M \cong L(\mathbb{F}_\infty)$ having standard invariant $\mathcal{P}$

Theorem (Yamagami, '03)

Given a countably generated rigid C^* tensor category, $\mathcal{C}$, there is an amalgamated free product factor M and a full subcategory of bifinite bimodules over M which is equivalent to $\mathcal{C}$.

Yamagami's factors are of the form $B *_A (A \otimes Q)$ for A and B hyperfinite II_1 algebras and $Q \neq \mathbb{C}$ an arbitrary finite von Neumann algebra. This algebra has property Γ so it is not an interpolated free group factor.

Our Result

Theorem (Brothier, H., Penneys, '12)

Given a countably rigid C^* tensor category, $\mathcal{C}$, there exists a full subcategory Bim of bifinite bimodules over $M_0 \cong L(\mathbb{F}_\infty)$ which is equivalent to $\mathcal{C}$.

The main ingredient is the use of planar algebras. They will be used both in the construction of the factor, M_0 , as well as the category of bimodules.

Unshaded planar tangles

Definition

Unshaded Planar tangles consist of three pieces of data.

- ▶ An external disk or rectangle D_0
- ▶ Finitely many internal subdisks or rectangles $D_1, \dots, D_n$
- ▶ Finitely many smoothly embedded strings whose colors are taken from a set of colors $\mathcal{L}$. Strings can not intersect each other and they intersect the disks transversely. Strings not intersecting disks are closed loops.
- ▶ Each disk comes with a distinguished marked interval.

An example

An example (contd.)

Planar algebras

Definition

Let Λ be the set of finite words on elements in $\mathcal{L}$. A planar algebra $P_\bullet$ with string labels $\mathcal{L}$ is a collection of vector spaces $(P_\alpha)_{\alpha \in \Lambda}$ with an action of planar tangles by multilinear maps satisfying:

- ▶ For each planar α_0 -tangle T , whose disks $D_i(T)$ are α_i -disks, there is a multilinear map

$$Z_T: \prod_{i=1}^s P_{\alpha_i} \rightarrow P_{\alpha_0}.$$

If S can be obtained from T by orientation preserving diffeomorphism, then $Z_S = Z_T$.

- ▶ Composition of tangles agrees with composition of the appropriate multilinear maps (Naturality).

Fantastic planar algebras

Definition

A fantastic (or factor) planar algebra is a planar algebra which satisfies the following additional properties:

- ▶ (Evaluable) P_α is finite dimensional for each $\alpha \in \Lambda$.
Furthermore, $P_\emptyset \cong \mathbb{C}$ with the empty diagram identified with $1 \in \mathbb{C}$. This forces each closed loop of color a to be a scalar δ_a .
- ▶ (Involutive) There is a conjugate-linear involution, $*$ taking P_α to $P_{\bar{\alpha}}$ where $\bar{\alpha}$ is the word α in the opposite order. This involution is compatible with reflection of tangles.
- ▶ (Spherical): For all $\alpha \in \Lambda$ and all $x \in P_{\alpha\bar{\alpha}}$, we have

$$\mathrm{tr}(x) = \begin{array}{c} \alpha \\ \square \\ \star \alpha \end{array} = \begin{array}{c} \alpha \\ \square \\ \star \alpha \end{array}$$

- (Positive): For every $\alpha \in \Lambda$, the map $\langle \cdot, \cdot \rangle: P_\alpha \times P_\alpha \rightarrow P_\emptyset \cong \mathbb{C}$ given by

$$\langle x, y \rangle = \begin{array}{c} \boxed{x} \text{---} \alpha \text{---} \boxed{y^*} \\ \star \qquad \qquad \star \end{array}$$

is a positive definite inner product. Hence for all $a \in \mathcal{L}$, $\delta_a > 0$ (in fact by Jones, $\delta_a \in \{2 \cos(\pi/n) : n \geq 3\} \cup [2, \infty)$).

- The operation

$$x \cdot y = \begin{array}{c} \alpha \\ | \\ \boxed{y} \\ | \\ \star \text{---} \alpha \\ | \\ \boxed{x} \\ | \\ \star \text{---} \alpha \end{array}$$

turns each $P_{\alpha\bar{\alpha}}$ into a finite dimensional C^* algebra. When diagrams are written with an α string on top and a β string on the bottom we say that they belong to the vector space $P_{\alpha \rightarrow \beta} (\cong P_{\alpha\bar{\beta}})$.

Examples

- ▶ The colored Temperley-Lieb algebra. P_α is the linear span of all planar string diagrams with no internal disks and outer color pattern α . The adjoint operation is the conjugate-linear extension of reflection of tangles.
- ▶ The noncommutative polynomial planar algebra, $\mathbb{C}\langle X_1, \dots, X_n \rangle$ with one string color. Here, $P_k = \mathbb{C}\{X_{i_1} \cdots X_{i_k}\}$, and the adjoint operation is the conjugate-linear extension of reflecting words. The action is as follows:

Examples (contd.)

$$Z \left(\begin{array}{c} \text{Diagram} \end{array} \right) (X_{i_1} X_{i_2} X_{i_3} X_{i_4} X_{i_5}, X_{j_1} X_{j_2} X_{j_3} X_{j_4} X_{j_5})$$

The diagram inside the large parentheses is a square containing several geometric elements: a smaller square in the upper-left, a circle in the lower-left, another square in the lower-right, and a quarter-circle in the upper-right. A curved line connects the right side of the upper-left square to the left side of the lower-right square. Three stars are placed within the diagram: one below the upper-left square, one to the left of the lower-left circle, and one to the left of the lower-right square. The large parentheses are preceded by the letter Z and followed by the product of two sequences of variables.

Examples (contd.)

$$Z \left(\begin{array}{c} \begin{array}{|c|c|c|} \hline i_3 & & i_4 \\ \hline i_2 & \square & i_5 \\ \hline i_1 & \star & \\ \hline \end{array} & \begin{array}{|c|} \hline k \\ \hline \end{array} \\ \hline \star & \begin{array}{|c|c|c|} \hline & j_3 & \\ \hline \bigcirc & \square & j_4 \\ \hline \star & j_1 & j_5 \\ \hline \end{array} \end{array} \right) (X_{i_1} X_{i_2} X_{i_3} X_{i_4} X_{i_5}, X_{j_1} X_{j_2} X_{j_3} X_{j_4} X_{j_5})$$

$$= n \cdot \delta_{i_5, j_3} \cdot \delta_{j_1, j_2} \cdot X_{i_1} X_{i_2} X_{i_3} X_{i_4} \left(\sum_{k=1}^n X_k^2 \right) X_{j_4} X_{j_5}$$

It is a direct check that $P_{k \rightarrow k}$ is isomorphic to $n^k \times n^k$ matrices over the scalars.

The category of projections, Pro associated to P

- ▶ We will now assume that $\star$ is in the lower left corner of a box unless otherwise marked.
- ▶ The objects are projections $p \in P_{\alpha \rightarrow \alpha}$ (i.e. $p = p^* = p^2$).
- ▶ We tensor objects in Pro by horizontal concatenation; e.g., if $p \in P_{\alpha \rightarrow \alpha}$ and $q \in P_{\beta \rightarrow \beta}$, then $p \otimes q \in P_{\alpha\beta \rightarrow \alpha\beta}$ is given by

$$\begin{array}{c} \boxed{p \otimes q} = \boxed{p} \boxed{q} \in P_{\alpha\beta \rightarrow \alpha\beta}. \\ \begin{array}{ccc} \begin{array}{c} | \alpha\beta \\ \hline \end{array} & \begin{array}{c} | \alpha \\ \hline \end{array} & \begin{array}{c} | \beta \\ \hline \end{array} \\ \begin{array}{c} \hline \\ | \alpha\beta \end{array} & \begin{array}{c} \hline \\ | \alpha \end{array} & \begin{array}{c} \hline \\ | \beta \end{array} \end{array} \end{array}$$

We extend the tensor product to direct sums of projections linearly.

- If $p \in P_{\alpha \rightarrow \alpha}$ and $q \in P_{\beta \rightarrow \beta}$, then elements in $\text{Pro}(p, q) = q(P_{\alpha \rightarrow \beta})p$ are all $x \in P_{\alpha \rightarrow \beta}$ such that $x = qxp$, i.e.,

We compose morphisms by vertical concatenation of elements in the planar algebra. Composition of matrices of morphisms occurs in the usual way.

- ▶ The *duality* operation on objects and morphisms is rotation by π

$$\boxed{\bar{p}} = \begin{array}{c} \text{---} \\ | \\ \boxed{\bar{p}} \\ | \\ \text{---} \end{array} = \begin{array}{c} \text{---} \\ | \\ \boxed{p} \\ | \\ \text{---} \end{array} = \begin{array}{c} \text{---} \\ | \\ \boxed{p} \\ | \\ \text{---} \end{array} .$$

Notice that if $p \in P_{\alpha \rightarrow \alpha}$ then $\bar{p} \in P_{\bar{\alpha} \rightarrow \bar{\alpha}}$.

- ▶ The *adjoint* operation in Pro is the identity on objects. The adjoint of a 1-morphism is the same as the adjoint operation in the planar algebra $P_{\bullet}$.
- ▶ The key fact (due to Jones, Yamagami, Morrison, Peters and Snyder) is that given a rigid C^* -tensor category, $\mathcal{C}$, then there is a fantastic planar algebra, $\mathcal{P}$, such that $\mathcal{C}$ is equivalent to Pro.

Guionnet, Jones, Shlyakhtenko type factors

- We define the graded algebra $\text{Gr}_\alpha(P_\bullet) = \bigoplus_{\beta \in \Lambda} P_{\bar{\alpha}\beta\alpha}$.
Multiplication $\wedge_\alpha$ is given by

$$x \wedge_\alpha y = \begin{array}{c} \begin{array}{c} | \beta \\ \boxed{x} \end{array} \begin{array}{c} | \gamma \\ \boxed{y} \end{array} \\ \alpha \quad \alpha \quad \alpha \end{array}$$

- The trace is given by

$$\text{tr}(x) = \frac{1}{\delta_\alpha} \cdot \begin{array}{c} \boxed{\Sigma CTL} \\ | \beta \\ \alpha \quad \boxed{x} \quad \alpha \\ \bigcirc \bar{\alpha} \end{array}$$

with CTL the set of colored Temperley-Lieb diagrams.

Proposition

The trace tr is positive definite on $\mathrm{Gr}_\alpha(P_\bullet)$ and multiplication is bounded with respect to the inner product induced by the trace. $\mathrm{Gr}_\alpha(P_\bullet)$ completes to a II_1 factor M_α . Furthermore, $M_0 \subset M_\alpha$ is of finite Jones index for any $\alpha \in \Lambda$ where the inclusion is given by

$$\boxed{x} \mapsto \underbrace{\boxed{x}}_\alpha,$$

- ▶ The proof involves an “orthogonalization” procedure, i.e. passing to an algebra where the different box spaces are orthogonal.
- ▶ It is straightforward to check that in the case $P_\bullet = \mathbb{C}\langle X_1, \dots, X_n \rangle$, the X_i form a free semicircular family under the trace on $\mathrm{Gr}_0(P_\bullet)$. Therefore, $M_0 \cong L(\mathbb{F}_n)$.

Bimodules over M_0

- Set $\text{Gr}_{\alpha,\beta}(P) = \bigoplus_{\beta \in \Lambda} P_{\bar{\alpha}\gamma\beta}$. It is spanned by boxes of the form

with inner product

- $\text{Gr}_0(P_\bullet)$ acts on the left by viewing $\text{Gr}_0(P_\bullet) \subset \text{Gr}_\alpha(P_\bullet)$ as above. There is an analogous right action.

Bimodules (contd.)

Proposition

Set $\mathcal{H}_{\alpha,\beta}$ to be the completion of $\text{Gr}_{\alpha,\beta}(P_\bullet)$. Then the $\text{Gr}_0(P)$ action extends to an M_0 action. We have an isomorphism of $M_0 - M_0$ modules $\mathcal{H}_{\alpha\beta,\emptyset} \cong \mathcal{H}_{\alpha,\bar{\beta}}$ where the mapping is given by the extension of

$$\begin{array}{c} \alpha \\ \hline \beta \end{array} \boxed{x} \mapsto \begin{array}{c} \alpha \\ \hline \boxed{x} \\ \hline \beta \end{array} .$$

Furthermore $\mathcal{H}_{\alpha,\beta}$ is a bifinite $M_0 - M_0$ module for any $\alpha, \beta \in \Lambda$.

Tensor product

Proposition

We have an isomorphism $\mathcal{H}_{\alpha,\emptyset} \otimes_{M_0} \mathcal{H}_{\emptyset,\beta} \rightarrow \mathcal{H}_{\alpha,\beta}$ given by the natural extension of

$$\begin{array}{c} \alpha \quad \boxed{\xi} \quad \otimes_{M_0} \quad \boxed{\eta} \quad \beta \\ \uparrow \quad \quad \quad \uparrow \\ \text{---} \quad \quad \quad \text{---} \end{array} \mapsto \begin{array}{c} \alpha \quad \boxed{\xi} \quad \boxed{\eta} \quad \beta \\ \uparrow \quad \quad \quad \uparrow \\ \text{---} \quad \quad \quad \text{---} \end{array}$$

- For $p \in P_{\alpha \rightarrow \alpha}$ we consider the bimodule $(\mathcal{H}_{\emptyset,\alpha})p$. We attach p at the bottom using the following identification:

$$\begin{array}{c} \uparrow \\ \boxed{\xi} \quad \bar{\alpha} \quad \boxed{p} \quad \bar{\alpha} \quad \text{---} \\ \longleftrightarrow \\ \begin{array}{c} \uparrow \\ \boxed{\xi} \\ \alpha \\ \boxed{p} \\ \alpha \end{array} \end{array}$$

We call this bimodule H_p . Notice $\bar{p}(\mathcal{H}_{\alpha,\emptyset}) \cong H_p \cong (\mathcal{H}_{\emptyset,\bar{\alpha}})p$.

The category of bimodules Bim over M_0

- ▶ The objects are the bimodules H_p and finite direct sums thereof.
- ▶ The tensor product is the Connes fusion product. Notice that $H_p \otimes_{M_0} H_q \cong H_{p \otimes q}$.
- ▶ $\text{Bim}(H_p, H_q)$ is the space of bimodule intertwiners.
- ▶ The contragredient bimodule of H_p is isomorphic to $H_{\bar{p}}$. This is achieved by reflection:

- Let $p \in P_{\alpha \rightarrow \alpha}$ and $q \in P_{\beta \rightarrow \beta}$. Notice that $x \in q(P_{\alpha \rightarrow \beta})p$ is naturally seen as an element in $\text{Bim}(H_p, H_q)$ via the mapping

We claim that all such intertwiners are of this form. Frobenius reciprocity implies that such intertwiners must be the $M_0 - M_0$ central vectors of $H_{\bar{p}} \otimes_{M_0} H_q$.

- These are the $M_0 - M_0$ central vectors of $p(\mathcal{H}_{\alpha,\beta})q$, i.e. the central vectors that are diagrammatically represented as:

These are exactly the diagrams with no strings on top.

This is used to prove the following theorem:

Theorem (Brothier, H., Penneys '12)

There is an equivalence of rigid C^* categories between Bim and Pro.

Theorem (Brothier, H., Penneys '12)

$\mathcal{P}$ can always be chosen to have infinitely many different colors.

This allows M_0 to always be isomorphic to $L(\mathbb{F}_\infty)$.

This is proved by writing M_0 as a compression of an amalgamated free product associated to the principal graph of $P_\bullet$.

Thank you for listening!
